You'll often want to come back to this dialog box because it's the starting point for many features. Figure 8-1: You can add any image to a new Photoshop document by choosing File**→New from Template. New Photoshop users are usually overwhelmed by the sheer volume of features and terminology they see. The faster you get past this initial learning curve, the more you'll use Photoshop to express your artistic vision. ## The Layers Panel As you create a new image, the layers window appears at the bottom of the workspace. (On the Mac, click the Layers panel button at the bottom right to display it.) You may see different windowpanes when you first open Photoshop, depending on the options you've selected. A Layers panel may also appear automatically when you create a new document and have not yet added any layers to it. Each layer has a unique color-coded icon and information label. Some layers, such as the Background and Crop layers, are color-coded according to color mode, whereas others are separate, making them easy to identify. Below, you see a simple, linear hierarchy of layers, with the top layer as the currently active layer. You may see many more layers than that. Your most recently created layers are saved into a stack called the History, as shown in Figure 8-2. Layers created at a specific time in the past are stacked together in this order on top of the current layer. If you group layers, you can reorganize them on the History panel. (In the future, Chapter 21 talks about the methods that can be used to manage layers.) FIGURE 8-2: The History panel shows you the most recently created layers. Figure 8-3 shows a typical Layers panel in the background, with an image named Clouds_f.png in the foreground. (If you take a look at Figure 8-3, you can see a few of the many layers in this image.) Layers are color-coded according to type, and the +

A central feature of heart failure (HF) is the loss of cardiac muscle fibers. This tissue loss is the result of apoptosis or necrosis, and the balance between these two modes of cell death, rather than the absolute levels of apoptosis, appears to be the critical determinant of the magnitude of the myocyte loss in HF. Three recent studies have shed considerable light on the process of necrosis in the failing heart. First, microarray analysis of gene expression in failing hearts revealed the upregulation of cyclophilin-D (CypD), a mitochondrial protein that protects the mitochondria from permeabilization and cell death, and a 4-fold increase in its expression in the failing heart. CypD has been implicated in the induction of necrosis through its binding to the mitochondrial inter membrane permeability transition pore (mPTP). Second, a recent study identified two new transcriptional regulators of CypD expression, the transcription factor FosB and the interferon regulatory factor 1 (IRF1). Both are upregulated in HF and overexpression of either gene in cardiomyocytes leads to an increase in CypD expression and protection from necrosis. Third, a new role for extracellular ATP (eATP) in the necrotic process was recently reported. In cardiac myocytes, eATP is released from injured cells
